Air Pollution and Noncommunicable Diseases
A Review by the Forum of International Respiratory Societies’ Environmental Committee, Part 2: Air Pollution and Organ Systems

Although air pollution is well known to be harmful to the lung and airways, it can also damage most other organ systems of the body. It is estimated that about 500,000 lung cancer deaths and 1.6 million COPD deaths can be attributed to air pollution, but air pollution may also account for 19% of all cardiovascular deaths and 21% of all stroke deaths. Air pollution has been linked to other malignancies, such as bladder cancer and childhood leukemia. Lung development in childhood is stymied with exposure to air pollutants, and poor lung development in children predicts lung impairment in adults. Air pollution is associated with reduced cognitive function and increased risk of dementia. Particulate matter in the air (particulate matter with an aerodynamic diameter < 2.5 μm) is associated with delayed psychomotor development and lower child intelligence. Studies link air pollution with diabetes mellitus prevalence, morbidity, and mortality. Pollution affects the immune system and is associated with allergic rhinitis, allergic sensitization, and autoimmunity. It is also associated with osteoporosis and bone fractures, conjunctivitis, dry eye disease, blepharitis, inflammatory bowel disease, increased intravascular coagulation, and decreased glomerular filtration rate. Atopic and urticarial skin disease, acne, and skin aging are linked to air pollution. Air pollution is controllable and, therefore, many of these adverse health effects can be prevented.

CHEST 2019; 155(2):417-426
Introduction

This second of a two-part report describes specific conditions associated with air pollution. The conditions are listed alphabetically. In addition to the text, Figure 1 presents associated organ systems, and Table 1 shows other effects of air pollution that are generally not associated with specific organs. It is important to note that for many of the diseases, the associations with exposures to air pollution in observational epidemiologic studies are not causal and may be subject to residual confounding due to other factors, such as smoking, lower socioeconomic status, and neighborhood factors. However, exposure dose and time relationships and animal studies corroborate and add strength to the conclusions from the epidemiologic studies.

Allergic and Immunologic Diseases

Allergic Sensitization and Rhinitis

It is well established that air pollution can exacerbate allergic responses in sensitized persons.1 Clinical epidemiologic studies show that ambient air pollution may also enhance allergic sensitization in children and increase IgE levels in the very young.2

There is considerable evidence that air pollution plays a role in both the development and the exacerbation of allergic rhinitis. A study of preschool-aged children found that exposure to traffic-related air pollution prenatally and in early life was associated with increased risk of allergic rhinitis.3 A study from China found a 10% and 11% increase in the incidence of medical utilization for allergic rhinitis among adults for each SD increase in particulate matter with an aerodynamic diameter < 2.5 μm (PM2.5) and nitrogen dioxide (NO2) levels, respectively.4

Environmental exposures may increase the risk of autoimmune diseases. The lung has an enormous surface area that comes into contact with a myriad of antigens. It has an efficient sensitization and antigen-presenting system that could make individuals prone to autoimmune disorders. Air pollution is a potential contributor to diseases such as rheumatoid arthritis and systemic lupus erythematosus.5,6 A Canadian study found increased odds of having a diagnosis of a rheumatic disease with increased ambient PM2.5 exposure.7 Air pollutants have also been implicated in triggering or exacerbating juvenile idiopathic arthritis,8 but autoimmunity related to air pollution exposure has largely been understudied.

Autoimmune Disease

| Brain: Stroke, Dementia, Parkinson’s Disease |
| Eye: Conjunctivitis, Dry Eye Disease, Blepharitis, Cataracts |
| Heart: Ischemic Heart Disease, Hypertension, Congestive Heart Failure, Arrhythmias |
| Lung: Chronic Obstructive Pulmonary Disease Asthma, Lung Cancer, Chronic Laryngitis, Acute and Chronic Bronchitis |
| Liver: Hepatic Steatosis, Hepatocellular carcinoma |
| Blood: Leukemia, Intravascular Coagulation, Anemia, Sickle Cell Pain Crises |
| Fat: Metabolic Syndrome, Obesity |
| Pancreas: Type I and II Diabetes |
| Gastrointestinal: Gastric Cancer, Colorectal Cancer, Inflammatory Bowel Disease, Crohn’s Disease, Appendicitis |
| Urogenital: Bladder Cancer, Kidney Cancer, Prostate Hyperplasia |
| Joints: Rheumatic Diseases |
| Bone: Osteoporosis, Fractures |
| Nose: Allergic Rhinitis |
| Skin: Atopic Skin Disease, Skin Aging, Urticaria, Dermographism, Seborrhea, Acne |

Figure 1 – Many conditions are associated with air pollution. This figure lists diseases linked to air pollution according to organ systems.
Bone Diseases

Environmental factors play a role in bone density and mineralization. To evaluate the effect of air pollution on bone structure and function, an analysis of > 9 million US Medicare enrollees found that osteoporosis-related bone fractures were statistically more common in areas of higher ambient PM2.5 concentrations. The effect was greater when only low-income communities were included in a sensitivity analysis.\(^8\)

The same investigators studied 692 middle-aged men with low incomes from the Boston Area Community Health Bone Survey cohort and found that exposures to ambient black carbon and PM\(_{2.5}\) were associated with markers of increased bone turnover and bone mineral loss.\(^8\) The National Health Insurance Research Database of Taiwan and the Taiwan Environmental Protection Agency found an association between exposure to carbon monoxide (CO) and NO\(_2\) and osteoporosis.\(^9\) The Oslo Health Study found that long-term air pollution exposure (PM and NO\(_2\)) was associated with a reduction in bone mineral density\(^10\) and fractures\(^11\) in elderly men.

Cancers

Outdoor air pollution has been classified as carcinogenic to humans by the International Agency for Research on Cancer based on evidence from epidemiologic and animal studies and mechanistic data.\(^12\) Many studies have shown an association between exposure to PM\(_{2.5}\) and particulate matter with an aerodynamic diameter < 10 \(\mu\)m (PM\(_{10}\)) and risk of lung cancer.\(^13\) In addition, NO\(_2\) and ozone (O\(_3\)) levels have been experimentally linked to cellular changes related to neoplasia: altered telomere length, expression of genes involved in DNA damage and repair, inflammation, immune and oxidative stress response, and epigenetic effects, such as DNA methylation.\(^14\)

Diesel engine exhaust has been identified by the World Health Organization as a carcinogen based on evidence of a link with lung cancer.\(^15,16\) Exposure to diesel exhaust or traffic pollution has also been associated with benign and malignant lung tumors in laboratory animals,\(^16\) colorectal cancer,\(^17\) and deaths from gastric cancer.\(^18\)

Air pollution exposure is implicated in both the incidence and mortality of bladder cancer. A Spanish study reported an association between emissions of polycyclic aromatic hydrocarbons and diesel exhaust and bladder cancer in long-term residents of an industrially polluted area.\(^19\) Studies from Taiwan have shown an increased risk of bladder cancer deaths.
associated with ambient benzene and other hydrocarbons from evaporative losses of petroleum products and motor vehicle emissions. Another study from São Paulo, Brazil, found an association between PM$_{10}$ exposure and risk of bladder cancer but not bladder cancer mortality. The American Cancer Society’s prospective Cancer Prevention Study II of 623,048 participants followed up for 22 years (1982-2004) found that PM$_{2.5}$ was associated with death from cancers of the kidney and bladder and that NO$_2$ levels were associated with colorectal cancer mortality.

Benzene exposure from vehicular exhaust, especially during the prenatal period and in the early years of childhood, has been associated with the risk of childhood leukemia. Prenatal exposure to PM$_{2.5}$ during pregnancy may increase a child’s risk of developing leukemia and astrocytomas.

Cardiovascular Diseases
Particulate air pollution has been strongly associated with an increased risk of cardiovascular disease mortality, myocardial infarction, stroke, and hospital admission for congestive heart failure and has been estimated to account for 19% of all cardiovascular deaths, 23% of all ischemic heart disease deaths, and 21% of all stroke deaths. A 10 µg/m$^3$ increase in PM$_{2.5}$ in a 2-day period was associated with an approximately 2% increase in myocardial infarctions and hospital admissions for heart failure in a 26-city US survey. Other studies have found similar associations between acutely increased ambient PM$_{2.5}$ and increases in mortality from myocardial infarction, stroke, heart failure, and hypertension. Mild increases in carboxyhemoglobin levels (in the 3%-6% range) can occur when individuals are exposed to traffic pollution and may trigger angina and arrhythmias in individuals with coronary heart disease. In Medicare recipients in nine US cities, PM concentrations during the 2 days prior to the event were associated with ischemic, but not hemorrhagic, stroke hospital admissions. This study also found a correlation between CO, NO$_2$, and sulfur dioxide (SO$_2$) levels and stroke.

In a separate article, the increased risk of stroke was greatest within 12 to 14 h of exposure to PM$_{2.5}$, and the relation held up even with PM$_{2.5}$ levels below those considered safe by the US Environmental Protection Agency. These acute effects of PM exposure are likely mediated by autonomic dysregulation, endothelial dysfunction, or thrombosis or a combination of these factors. Many studies have found that cardiovascular parameters such as heart rate variability are associated with air pollution, especially exposure with PM$_{2.5}$. A decrease in heart rate variability, as occurs with air pollution exposure, is associated with many poor health outcomes, such as an increased risk of adverse cardiovascular events and all-cause mortality in selected populations. Long-term effects of exposure to air pollution on the risk of cardiovascular diseases have been well documented. These effects can shorten life expectancy even at relatively low PM levels. Studies have found a relationship between air pollution and atherosclerosis, which is a central mechanism for ischemic heart disease and stroke and may explain the long-term effects of pollution on risk of many cardiovascular diseases. The relationship of PM and ischemic mortality seems to vary with the composition and source of the PM$_{2.5}$; the most damaging PM$_{2.5}$ may come from coal combustion.

Cognitive Function and Neurologic Diseases
Air pollution has deleterious effects on the CNS, including impairment of cognitive function and increased risk of dementia and stroke in older adults. A Canadian study of 4.4 million people showed that the risk of dementia was correlated in a “dose-dependent” manner with distance from a major roadway. People living within 50 meters had a hazard ratio of 1.07, whereas those living 50 to 100 meters away had a hazard ratio of 1.04, and those living 101 to 200 meters away had a hazard ratio of 1.02 compared with those living >300 meters from a major roadway. Living near a busy roadway is a marker of air pollution exposure. Inflammation in the bloodstream in response to pollutants has been found to cause systemic vascular (including cerebral vascular) dysfunction. Studies in animals have shown that inhaled ultrafine particles can travel from the nose via the olfactory nerve directly into the brain, where they may cause inflammation and oxidative stress.

Air pollution can damage the developing brain, which is especially concerning because this damage can impair cognitive function across the life span. Many studies have found that prenatal and early childhood exposure to PM$_{2.5}$ is associated with delayed psychomotor development and lower child intelligence. A study in Mexico City found that children living in more polluted areas had worse cognitive performance and more prefrontal brain lesions on MRI. In the same article, the authors reported that dogs exposed to comparable levels
of pollution had similar prefrontal lesions and deposits of ultrafine particles within those lesions. More than 1,000 articles have been written on air pollution and autism, which has been associated with exposure to polycyclic aromatic hydrocarbons, diesel exhaust, PM, CO, NO₂, O₃, and SO₂ in prenatal or early life, and there are several animal studies to support these findings. However, many studies have not found associations, and there is a lack of consistency on the pollutant.

Air pollution is also harmful to the aging brain. Older adults more heavily exposed to air pollution perform more poorly on cognitive testing and are at increased risk of dementia compared with less exposed adults. Long-term exposure to PM₂.₅ was associated with a smaller brain volume according to MRI (an indicator of brain aging) and higher odds of subclinical strokes among generally healthy adults. Short-term exposure to fine particles increased the risk of hospitalizations and all-cause mortality in Parkinson’s disease.

Diabetes, Obesity, and Endocrine Diseases
Evidence from several studies links air pollution and type 2 diabetes mellitus. PM₂.₅ and NO₂ exposures are associated with prevalence of diabetes and increased glycosylated hemoglobin levels among both diabetic and non-diabetic individuals. There is also a higher morbidity and mortality related to ambient air pollution among patients with diabetes. Several studies have described increased risk for metabolic syndrome in adults exposed to high ambient PM₁₀. It seems that air pollution affects accumulation of visceral adipose tissue or brown to white adipose tissue transition, which may worsen insulin resistance, oxidative stress, and systemic inflammation.

Several metabolic changes affecting fat deposition occur with exposure to air pollution. Children in Mexico City exposed to high PM₂.₅ levels had higher leptin and endothelin-1 levels and lower glucagon-like peptide-1, ghrelin, and glucagon levels compared with those living in low PM₂.₅ areas. Leptin was strongly correlated to PM₂.₅ cumulative exposures. Residing in a high PM₂.₅ and O₃ environment was associated with 12-h fasting hyperleptinemia, altered appetite-regulating peptides, vitamin D deficiency, and increases in endothelin-1 in healthy children. Air pollution-associated glucose and lipid dysregulation seem to be mediated through pathways that increase insulin resistance. Children living in areas with more traffic-related air pollution have been found to have a higher BMI after adjusting for confounders, which may be a consequence of metabolic changes, including insulin resistance in response to pollution exposure.

Eye Diseases
Tearing and ocular irritation may occur as a reaction to visible haze, and this finding is often worse for contact lens wearers. Conjunctivitis is most associated with O₃ and NO₂ exposure, although PM₁₀ and SO₂ are also correlated. Cataract formation has been described in women exposed to household air pollution in low-income countries. O₃ levels and decreased humidity have been associated with dry eye disease. Air pollution, specifically PM and CO, have been associated with acute worsening of blepharitis.

GI Diseases
Although less investigated, air pollution has been linked to several GI conditions, including inflammatory bowel disease, enteritis, gastric ulcer, and appendicitis. A case-control study of chronic pollution exposure in the United Kingdom found that younger individuals were more likely to have Crohn’s disease if they lived in areas with high NO₂ or SO₂ levels, although there was no overall association between exposure to air pollutants and risk of inflammatory bowel disease. Other studies, however, have suggested a possible link to inflammatory bowel disease.

A small number of studies have found associations between short-term exposure to pollution and acute episodes of enteritis, gastric ulcer disease, and appendicitis. A Chinese study of > 12,000 hospital visits for enteritis found that PM₁₀, PM₂.₅, NO₂, SO₂, and CO levels were significantly elevated on days of outpatient visits, whereas O₃ was not. Lag models showed that the pollution association was most prominent on the day of admission. A study of elderly Hong Kong Chinese subjects found that long-term exposure to PM₂.₅ was associated with hospitalizations for gastric ulcer disease. A Canadian study of the 7-day accumulated average of ground level O₃ showed a modest correlation with perforated appendicitis.

Hematologic Diseases
It has been known since the 1970s that air pollution containing lead from gasoline causes anemia. Other pollutants released during fuel combustion may also
contribute to hematologic disease, either by directly entering the bloodstream following inhalation, or by activating inflammatory pathways in the lung that then result in intravascular inflammation. PM$_{2.5}$ promotes an imbalanced coagulative state through platelet and endothelial activation by inflammatory cytokines. These increase the risk of thrombotic events, including myocardial infarction, stroke, and most likely DVT and pulmonary embolism.

Exposure to lead in air pollution affects the formation of hemoglobin. Indoor air pollution has been shown to be a risk factor for anemia in young children as well as the elderly. Air pollution may increase hemoglobin distortion in sickle cell disease. The resulting microvascular obstruction leads to lack of oxygen and severe pain. Poor air quality, including increased O$_3$ levels, has been correlated with ED visits for sickle cell pain crises.

Liver Diseases

Living near a major roadway, which is associated with increased air pollution, is linked to an increased prevalence of hepatic steatosis. There are several potential reasons for this link as air pollution has many damaging effects on liver cells through inflammatory mediators, genotoxicity, mitochondrial damage, and damage to other organs, which affect the liver secondarily. The liver is the main detoxifying organ, and a variety of substances that enter the body, including toxic components on PM, are presented to the liver for catabolism.

An Taiwanese study of 23,820 persons followed up for a median of 16.9 years found that exposure to PM$_{2.5}$ was associated with an increased risk of hepatocellular cancer. These investigators also recorded elevated alanine aminotransferase levels and hypothesized that carcinoma may result from chronic inflammation. A Chinese study found that high PM$_{2.5}$ exposure following the diagnosis of hepatocellular carcinoma was associated with shortened survival in a dose-dependent manner.

Alpha$_1$-antitrypsin deficiency is a genetic disorder associated with decreased release from the liver of the enzyme that catabolizes the proteolytic enzyme products of inflammation. Persons with this disorder are more susceptible to the detrimental effects of inflammation. Exposure to O$_3$ and PM$_{10}$ was associated with a more rapid decline of lung function in the persons with the PiZZ variant of this disease.

Renal Diseases

The kidney, a highly vascular organ, is vulnerable to both large and small vessel dysfunction and is therefore likely to be susceptible to the oxidative stress and systemic inflammatory effects of air pollution exposure. Animal models have shown that breathing diesel exhaust fumes exacerbates chronic renal failure by worsening renal oxidative stress, inflammation, and DNA damage. Living closer to a major highway has been found to be associated with a lower estimated glomerular filtration rate; the association of decreased renal function with pollution was greater for exposure to PM.

Respiratory Diseases

The respiratory tract is the main organ affected by air pollution and the most studied: there are more than 13,000 entries in PubMed for air pollution and respiratory disease. Ambient air pollution is estimated to cause the death of > 800,000 persons from COPD and 280,000 persons from lung cancer. Indoor air pollution is estimated to cause the death of > 750,000 persons from COPD and 300,000 persons from lung cancer, making the toll for both forms of air pollution 1.6 million deaths for COPD and > 500,000 for lung cancer. There is overlap in the two forms of pollution and the two diseases.

Air pollution also causes breathlessness in most patients with severe chronic respiratory diseases. Air pollutants can affect all parts of the respiratory system and throughout a person’s life cycle. As discussed in Part 1 of this report, prenatal exposure to air pollutants is associated with wheezing and asthma in early childhood. The rate of lung function growth in childhood is decreased by exposure to pollutants and is a predictor of adult lung disease. Among adults, long-term exposure to air pollution is a risk for accelerated lung function decline with aging. Childhood exposure to air pollution has been linked to the risk of asthma in many studies, and pollution exposure has also been found to increase the incidence of asthma in adults, although the evidence for this theory is less consistent.

In addition to asthma, air pollution is associated with the risk of COPD, lung cancer, and chronic laryngitis. It may be a factor in transforming asthma into COPD. Household air pollution may be more hazardous than outdoor air pollution because of the concentration and duration of exposure; it is a major risk factor for COPD and chronic bronchitis in low-income countries.
Air pollutants are also well-known triggers of respiratory disease exacerbations. Many different pollutants, such as $O_3$, $PM_{2.5}$, $SO_2$, and $NO_2$, have irritant effects that can induce cough, phlegm, and bronchial hyperresponsiveness. Increases in $PM$ levels are associated with increased visits to the ED for asthma, COPD, and respiratory symptoms that are often attributed to respiratory infections.

### Skin Diseases

Several biologic parameters affecting skin quality are influenced by pollution, such as change in sebum excretion rate and composition, level of carbonylated proteins in the stratum corneum, and a higher erythematous index on the face of highly exposed subjects. The change in sebum may be a cause for increased acne occurring with air pollution.

Several skin diseases have been associated with air pollution. A multicenter study found that air pollution was associated with a higher frequency of atopic and urticarial skin disease, dermographism, and seborrhea (but a lower frequency of dandruff). Urticaria is among the skin pathologies that have been associated with pollution. ED visits for urticaria have been correlated with poorer air quality over a 2- to 3-day lag. A number of studies have found positive associations between air pollution and prevalence and exacerbations of eczema, primarily in children with traffic-related exposures.

Outdoor and indoor air pollution exposure has been associated with increased skin aging after controlling for sun exposure, smoking, and other confounders. Cooking with solid fuels was associated with 5% to 8% more severe wrinkle appearance on the face and a 74% increased risk of having fine wrinkles on the dorsal surface of hands independent of age and other influences on skin aging.

### The Role of the Health-Care Provider

Assessing exposure by primary care providers may be difficult because the source of air pollution varies between communities and within household situations. Studies on indoor air pollution use extensive surveys to report on smoke exposure, burning conditions, and symptoms during cooking and household work. Research on outdoor air pollution relies on monitoring of the individual pollutants by sophisticated means, including personal monitors. For primary care health-care providers, simply asking a few questions and documenting the answers in the medical record can help gauge the extent of exposure. For indoor air pollution, asking what type of fuel is used, how the home is ventilated, and how much time is spent around the fire may provide important information. For outdoor air pollution exposure, the questions should center around the proximity to sources of pollution (usually industrial and roadway) and exposure time.

In advising patients, avoidance is the most important intervention; almost any means that reduce air pollution may be beneficial. Much international effort has gone into developing and deploying better household stoves. Reducing cookstove toxic emissions reduced BP in pregnant women at their regular prenatal visits. The reduction was greatest in those who had hypertension.

Personal respirators (facemasks) can reduce inhaled particulates. Wearing personal respirators while being active in central Beijing reduced BP and heart rate variability, markers associated with cardiovascular morbidity. The beneficial effects of personal respirators extended to other cardiovascular markers and were almost immediate and lasted during the exposure time.

Air purifiers also reduce PM. Air purification for just 48 h significantly decreased $PM_{2.5}$ and reduced circulating inflammatory and thrombogenic biomarkers as well as systolic and diastolic BPs. In another study, air filtration improved endothelial function and decreased concentrations of inflammatory biomarkers but not markers of oxidative stress.

Last, health-care workers are often influential members of communities, and it is their duty to advocate for clean air on behalf of their patients. Their influence can mobilize the attitudes of communities to cleaner and safer air.

### Summary and Resolve

Air pollution is one of the most important avoidable risks to health globally. Air pollution has been termed the “silent killer” by the World Health Organization because its effects often go unnoticed or are not easily measured. Even when there is organ harm, it is usually attributed to an unknown or chance malfunction of that organ. Although the lungs have been the most studied organ, air pollution affects most systems. Many studies have found harmful effects of air pollution on a continuum of exposure that extends down into levels considered safe by national standards.
The good news is that the problem of air pollution can be addressed and ameliorated. Improving air quality may have almost immediate benefit, seen as increased infant birth weight with the 2008 Beijing Olympics,114 improved lung-function growth in children in the Children’s Health Study,10 and improved mortality seen in the Harvard Six Cities study.115 Improving air quality, then, may give us better and longer lives in a relatively short time.116
